Field Report: Edge Cache Rollout

Prepared for the platform team. All numbers in this sample are made up.

1. Summary

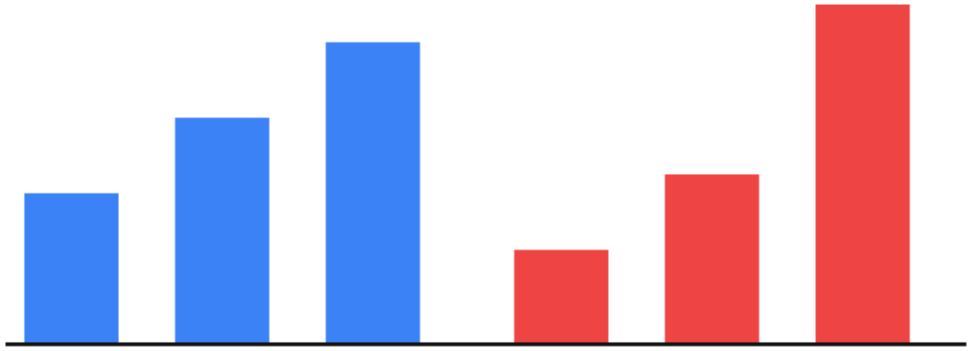

The edge cache cut median latency from 180 ms to 42 ms in the first week. We measured latency at three regions and kept the slowest one as the baseline. Cold starts still add latency on the first request after a deploy.

The photo above is a raster image. In dark mode the page turns dark, but the photo keeps its colors.

2. Results

The edge cache cut median latency from 180 ms to 42 ms in the first week. We measured latency at three regions and kept the slowest one as the baseline. Cold starts still add latency on the first request after a deploy. The edge cache cut median latency from 180 ms to 42 ms in the first week. We measured latency at three regions and kept the slowest one as the baseline. Cold starts still add latency on the first request after a deploy.

2.1 Latency by region

Region	Before	After
Frankfurt	170 ms	39 ms
Singapore	210 ms	51 ms
Virginia	160 ms	36 ms

3. Next steps

The edge cache cut median latency from 180 ms to 42 ms in the first week. We measured latency at three regions and kept the slowest one as the baseline. Cold starts still add latency on the first request after a deploy.

- Warm the cache after each deploy.
- Alert when p95 latency passes 120 ms.

Appendix A. Method

The edge cache cut median latency from 180 ms to 42 ms in the first week. We measured latency at three regions and kept the slowest one as the baseline. Cold starts still add latency on the first request after a deploy. The edge cache cut median latency from 180 ms to 42 ms in the first week. We measured latency at three regions and kept the slowest one as the baseline. Cold starts still add latency on the first request after a deploy. The edge cache cut median latency from 180 ms to 42 ms in the first week. We measured latency at three regions and kept the slowest one as the baseline. Cold starts still add latency on the first request after a deploy.
